(54) Optical deflector

(57) There is disclosed an optical deflector (200) comprising a mirror structure (210) having first and second surfaces in a front/back relation, a single plate base (230) for holding the mirror structure (210), and a driver (220, 260, 262, 268) for driving the mirror structure (210). The mirror structure (210) comprises a pair of supports (212), a movable plate (214), and a pair of elastic members (216) for connecting the movable plate (214) and the supports (212), such that the movable plate (214) is able to rock with respect to the supports (212). The movable plate (214) has a mirror surface (218) on the second surface. The base (230) has an opening (234) for exposing the mirror surface (218). The supports (212) of the mirror structure (210) are fixed to the base (230) with the second surfaces of the supports (212) in contact therewith. The driver (220, 260, 262, 268) includes a conductive element (220) formed on the first surface of the movable plate (214), and magnetic field generating elements (268) fixed on the base (230).

FIG. 1

EP 1 207 416 A1

Description

[0001] The present invention relates to an optical deflector which changes a direction of a mirror surface irradiated with a light beam to change the direction of a reflected light beam.

[0002] A concept of manufacturing an optical deflector by silicon micro-machining was presented by K. Petersen around 1980. In recent years, a practical optical deflector has been developed, and a remarkable progress has also been made in a manufacturing process.

However, presently, it cannot be said that there is an established method regarding a mounting technique.

[0003] The present applicant has disclosed an electromagnetic driving type optical deflector in U.S. Patent No. 6,122,089. This deflector will be described hereinafter with reference to FIGS. 13 to 15.

[0004] The optical deflector includes an optical deflector mirror portion 100 formed of a single-crystal silicon substrate, and the optical deflector mirror portion 100 includes a movable plate 101, a pair of elastic members 102 and a pair of supports 103. The movable plate 101 has a driving coil 104 on a lower surface thereof (lower surface in FIGS. 14 and 15), and a mirror surface 106 on an upper surface thereof (upper surface in FIGS. 14 and 15).

[0005] As shown in FIG. 15, the support 103 of the optical deflector mirror portion 100 is bonded/fixed to a U-shaped fixing member 111. In order to prevent the fixing member 111 from blocking a light beam incident upon the mirror surface 106 and a light beam reflected by the mirror surface 106, the optical deflector mirror portion 100 is attached to the fixing member 111 in such a manner that the surface of the movable plate with the driving coil 104 formed thereon necessarily turns to the fixing member.

[0006] The optical deflector further includes a magnetic circuit including a permanent magnet 108 and magnetic yokes 109, 110. As shown in FIG. 14, the magnetic yoke 110 extends in the vicinity of the movable plate 101 through the fixing member 111 in order to apply a high magnetic field to the driving coil 104.

[0007] In mirror structures such as the optical deflector mirror portion 100, the surface of the support on a driving coil side is utilized as a bonding surface with the fixing member. Since a power supply pad for the driving coil is usually formed on the surface of the support on the driving coil side, it is difficult to secure a flat surface with an area sufficient for bonding.

[0008] Moreover, in the mirror structure the support is bonded to the fixing member with the power supply pad directed to the fixing member. Therefore, in order to draw wiring out of the power supply pad, an anisotropic conductive film (ACF), and the like need to be used to connect wiring materials such as a flexible wiring board (FPC) to the mirror structure before bonding the structure to the fixing member. This restriction deteriorates

operation efficiency during bonding to the fixing member, and also deteriorates positioning precision.

[0009] Furthermore, since the surface of the mirror structure on the driving coil side is attached to the fixing member, the magnetic yoke or the fixing member needs to be processed in a complicated shape in order to dispose the magnetic yoke in the vicinity of the driving coil.

[0010] An object of the present invention is to provide an optical deflector superior in manufacturing properties. Another object of the present invention is to provide an optical deflector in which a mirror structure can be mounted with high reliability, satisfactory operation efficiency, and high positioning precision. A further object of the present invention is to provide an optical deflector in which a magnetic circuit can easily be prepared and attached.

[0011] According to the present invention, there is provided an optical deflector comprising: a mirror structure; a base for holding the mirror structure; and driving means for driving the mirror structure. The mirror structure comprises a pair of supports fixed to the base, a movable plate which is moved with respect to the support, and a pair of elastic members for connecting the movable plate to the support. The movable plate can rock with respect to the support using the pair of elastic members as a rocking axis. The mirror structure has a first surface and a second surface in a front/back fashion, the driving means includes a conductive element formed on the first surface of the movable plate, the movable plate has a mirror surface formed on the second surface, the supports are fixed to the base with the second surface of the supports in contact with the base, and the base has an opening for exposing the mirror surface.

[0012] The supports preferably comprise electrode pads electrically connected to the conductive element, the base has wiring materials for electric connection to the outside, the wiring materials have connection portions electrically connected to the electrode pads, and the electrode pads are electrically connected to the connection portions by wire bonding.

[0013] The conductive element is, for example, a coil extending along a peripheral edge of the movable plate, the driving means has a magnetic circuit for applying a magnetic field to the coil, and the movable plate is driven using an electromagnetic force acting between the coil and the magnetic circuit. The magnetic circuit comprises a pair of permanent magnets and a yoke of magnetic material, and at least a part of the yoke is disposed in the vicinity of the first surface of the movable plate.

[0014] This summary of the invention does not necessarily describe all necessary features so that the invention may also be a sub-combination of these described features.

[0015] The invention can be more fully understood from the following detailed description when taken in conjunction with the accompanying drawings, in which:

[0016] FIG. 1 is an exploded perspective view of an

electromagnetic driving type optical deflector according to one embodiment of the present invention.

[0017] FIG. 2 is an enlarged perspective view of a mirror chip of FIG. 1.

[0018] FIG. 3 is an enlarged perspective view of a wiring substrate of FIG. 1, showing that a lead wire is connected to the wiring substrate.

[0019] FIG. 4 is an enlarged perspective view of the wiring substrate of FIG. 1, showing that a flexible substrate is integrally formed with the wiring substrate.

[0020] FIG. 5 is a perspective view showing the mirror chip before being assembled.

[0021] FIG. 6 is a perspective view of a base to which the mirror chip before assembly in FIG. 5 is bonded.

[0022] FIG. 7 is a perspective view of the base whose support of the mirror chip before assembly in FIG. 6 is partially removed.

[0023] FIG. 8 is an enlarged perspective view of a magnetic circuit of FIG. 1.

[0024] FIG. 9 is a plan view of the magnetic circuit of FIG. 8.

[0025] FIG. 10 is a perspective view of an assembled state of the optical deflector shown in FIG. 1.

[0026] FIG. 11 is a sectional view of the optical deflector taken along line XI-XI of FIG. 10.

[0027] FIG. 12 is also a sectional view of the optical deflector taken along line XI-XI of FIG. 10, in which some parameters about mirror, permanent magnet, and base are entered.

[0028] FIG. 13 is a plan view of a prior-art optical deflector.

[0029] FIG. 14 is a sectional view of the optical deflector taken along line A-A of FIG. 13.

[0030] FIG. 15 is a sectional view of the optical deflector taken along line B-B of FIG. 13.

[0031] Embodiments of the present invention will be described hereinafter with reference to the drawings.

[0032] An electromagnetic driving type optical deflector according to the embodiment of the present invention is shown in FIG. 1. As shown in FIG. 1, an optical deflector 200 includes a mirror chip 210 as a mirror structure, a base 230 for holding the mirror chip 210, and a magnetic circuit 260 for driving the mirror chip 210.

[0033] As shown in detail in FIG. 2, the mirror chip 210 includes a pair of supports 212, a movable plate 214 which is moved with respect to the supports 212, and a pair of elastic members 216 for connecting the movable plate 214 to the supports 212. The movable plate 214 can rock with respect to the supports 212 about the pair of elastic members 216 as a rocking axis. In other words, the movable plate 214 is rockably center-supported with respect to the supports 212 by the pair of elastic members 216.

[0034] The mirror chip 210 has two surfaces which are in a front/back relation, for example, a first surface seen in FIG. 2, and a second surface as a back side of the first surface. The movable plate 214 includes a conductive element 220 formed on the first surface, and a mirror

surface 218 formed on the second surface. The conductive element 220 is, for example, a coil disposed along a peripheral edge of the movable plate 214, which is not limited.

[0035] The pair of supports 212 include a pair of electrode pads 224. One (left) electrode pad 224 is electrically connected to an outer end of the coil 220 via a wiring 226 extending through one (left) elastic member 216. The other (right) electrode pad 224 is electrically connected to an inner end of the coil 220 via a wiring 227 extending through the other (right) elastic member 216 and a jump wiring 228 crossing over the coil 220 disposed along the peripheral edge of the movable plate 214.

[0036] The mirror chip 210 is prepared from a single-crystal silicon substrate, for example, using a semiconductor manufacturing technique. That is, the coil 220, electrode pad 224, and wirings 226, 227 are formed as plane circuit elements in planar shapes, and the jump wiring 228 is formed, for example, utilizing a multilayered wiring technique. However, the mirror chip 210 is not limited to this. For example, in addition to the single-crystal silicon substrate, other materials such as polycrystalline silicon, silicon compounds, and organic materials may be used to prepare the chip. Moreover, the chip may be prepared from substrates other than the single-crystal silicon substrate. Furthermore, the chip may be prepared by techniques other than the semiconductor manufacturing technique.

[0037] As shown in FIG. 1, the base 230 comprises a main substrate 232, a pair of bonding portions 236 to which the mirror chip 210 is bonded, a pair of attachment portions 238 to which the magnetic circuit 260 is attached, and a rigid substrate 240 fixed to the main substrate 232. The main substrate 232 has an opening 234 for exposing the mirror surface 218 formed on the movable plate 214 of the mirror chip 210.

[0038] The main substrate 232 has a plane 232a, which faces the second surface of the mirror chip 210. Each of the bonding portions 236 projects from the plane 232a of the main substrate 232, and has a flat bonding surface 236a disposed substantially in parallel to the plane 232a. Similarly, each of the attachment portions 238 projects from the plane 232a of the main substrate 232, and has a flat attachment surface 238a disposed substantially in parallel to the plane 232a. The bonding portions 236 and attachment portions 238 are integrally formed, for example, with the main substrate 232, but may be separate members fixed to the main substrate 232 by means such as adhesion.

[0039] The rigid substrate 240 is a wiring substrate having wirings for electric connection to the outside. The wiring substrate 240 is within the plane 232a of the main substrate 232. That is, the wiring substrate 240 does not project from the main substrate 232. This effectively prevents disconnection by contact with other members during assembly of the optical deflector. The wiring substrate 240 is elongated and extended substantially in a

U shape, and has opposite ends thereof positioned in the vicinity of the bonding portions 236.

[0040] As shown in FIG. 3, the wiring substrate 240 includes a pair of wirings 242 for electric connection to the electrode pads 224 of the mirror chip 210, and a ground wiring (GND wiring) 244 for grounding. The pair of wirings 242 extend along the wiring substrate 240, and have opposite ends electrically connected to bonding pads 246 positioned on ends of the wiring substrate 240.

[0041] The GND wiring 244 is connected to a GND pad disposed on the front side of the wiring substrate 240, and is further connected to a GND pad disposed on the back side of the wiring substrate 240 via a through hole. For example, the main substrate 232 has conductivity, the wiring substrate 240 is fixed to the main substrate 232 using a conductive adhesive, and the GND pad on the back side of the wiring substrate 240 is electrically connected to the main substrate 232.

[0042] In FIG. 3, the respective wirings 242, 244 of the wiring substrate 240 are soldered and connected to a flexible lead wire 252 for electric connection to external apparatuses such as a driving control circuit. That is, the base 230 has the flexible lead wire 252 connected to the wirings 242, 244 of the wiring substrate 240. The wiring substrate 240 is connected to the external apparatuses of the optical deflector, such as the driving control circuit, via the lead wire 252. The connection to the external apparatus using the lead wire 252 is appropriate for the optical deflector which is relatively distant from the external apparatus. When a length of the lead wire 252 is adjusted, the connection can advantageously be applied to a broad range of layouts of the optical deflector and external apparatus.

[0043] However, a mode of electric connection to the external apparatus is not limited to this. For example, as shown in FIG. 4, the wirings 242, 244 of the wiring substrate 240 may electrically be connected to a flexible substrate 254 formed integrally with the wiring substrate 240. That is, the base 230 may include the flexible substrate 254 integrally formed with the wiring substrate 240. The wiring substrate 240 is connected to the external apparatus via the flexible substrate 254. The connection to the external apparatus using the flexible substrate 254 is appropriate for the optical deflector which is disposed in the vicinity of the external apparatus. This has an advantage that connecting operations required for the lead wire, such as a soldering operation, are unnecessary.

[0044] A mirror chip 210A before assembly is shown in FIG. 5. The mirror chip 210A before assembly includes a frame-shaped support 212A which surrounds the movable plate 214. As shown in FIG. 6, when a part of the second surface of the support 212A is bonded to the bonding surfaces 236a (see FIG. 1) of the bonding portions 236, the mirror chip 210A before assembly is fixed to the base 230. Thereafter, as shown in FIG. 7, unstable portions of the support 212A of the mirror chip

210A before assembly, which are not fixed to the bonding portions 236, that is, a pair of portions of the support extending in parallel to the elastic member 216 are removed. As a result, the mirror chip 210A before assembly, which has the frame-shaped support 212A, constitutes the mirror chip 210 having the pair of supports 212.

[0045] When a grooves are formed beforehand in portions to be cut, and the unnecessary portions are broken along the groove, the support 212A can partially be removed easily and steadily. The grooves are formed by a half cut in etching or dicing (cutting only a part of a wafer thickness). As described in detail in USP 6,122,089, this system is effective for disposing a permanent magnet of the magnetic circuit 260 assembled later in the vicinity of the movable plate 214.

[0046] Furthermore, as shown in FIG. 6, the electrode pads 224 of the mirror chip 210 are connected to the bonding pads 246 of the wiring substrate 240 by wire bonding. That is, the electrode pads 224 of the mirror chip 210 are electrically connected to the bonding pads 246 of the wiring substrate 240 by bonding wires 248. Additionally, the bonding wires 248 are preferably sealed by resin (not shown) in order to enhance reliability.

[0047] As shown in FIGS. 8 and 9, the magnetic circuit 260 comprises a yoke 262 of magnetic material, and a pair of permanent magnets 268. The yoke 262 has an outer yoke 264 having a rectangular frame shape, and an inner yoke 266 crossing a middle of an inner space. That is, the yoke 262 has a pair of rectangular through holes. The yoke 262 is formed, for example, by partially hollowing out the rectangular magnetic material, and making two rectangular through holes.

[0048] The pair of permanent magnets 268 are contained in a pair of through holes of the yoke 262, and fixed in contact with the outer yoke 264. As a result, gaps 270 are formed between the respective permanent magnets 268 and the inner yoke 266. The gaps 270 are called a magnetic gap. The magnetic circuit 260 having this inner yoke 266 has a higher magnetic flux density in the magnetic gap 270 as compared with a circuit having no inner yoke.

[0049] As shown in FIGS. 10 and 11, the magnetic circuit 260 is fixed to the attachment portions 238 of the base 230. As shown in FIG. 11, this fixing is realized, for example, by bonding a part of the yoke 262 to the attachment surfaces 238a of the attachment portions 238. That is, the magnetic circuit 260 is attached to the base 230 on the same side as a side on which the mirror chip 210 is disposed.

[0050] As shown in FIG. 11, the inner yoke 266 is positioned in the vicinity of a middle of the movable plate 214, and in the vicinity of the first surface of the movable plate 214 with the coil 220 formed thereon. Moreover, each of the permanent magnets 268 has a surface 268a closest to the main substrate 232, and a surface 268b remotest from the main substrate 232. The coil 220 of the movable plate 214 is positioned between the surfac-

es 268a and 268b of the permanent magnets 268 with respect to a direction of a normal to the surface 232a of the main substrate 232. In other words, the coil 220 is positioned so as to overlap the permanent magnets 268 as viewed from a direction parallel to the first and second surface of the mirror chip 210.

[0051] As a result, the coil 220 is substantially positioned in the magnetic gaps 270 between the permanent magnets 268 and the inner yoke 266 both with respect to a vertical direction to the surface 232a of the main substrate 232 and a direction extending in parallel to the vertical direction and crossing at right angles to the elastic members 216, that is, the rocking axis. The position of the coil in the vertical direction is particularly important. If the position deviates from the magnetic gaps 270, the magnetic flux density rapidly decreases. By this arrangement, the coil 220 is disposed in a high magnetic flux density.

[0052] The magnetic circuit 260 fixed to the base 230 and the coil 220 formed on the movable plate 214 constitute electromagnetic driving means for driving the mirror chip 210. In other words, the optical deflector 200 comprises electromagnetic driving means for driving the mirror chip 210. The driving means comprises the coil 220 extending along the peripheral edge of the movable plate 214, and the magnetic circuit 260 for applying the magnetic field to the coil 220. The movable plate 214 is driven by an electromagnetic force acting between the coil 220 and the magnetic circuit 260, and the direction of the plate can appropriately be changed.

[0053] As shown in FIGS. 10 and 11, the mirror surface 218 formed on the second surface of the movable plate 214 is exposed via the opening 234 formed in the main substrate 232 of the base 230. The mirror surface 218 of the movable plate 214 is illuminated with a light beam Bi through the opening 234. A direction of a light beam Br reflected by the mirror surface 218 is changed in accordance with the direction of the movable plate 214, that is, the beam is deflected.

[0054] The opening 234 of the base 230 preferably has a size that does not intercept the light beam incident upon the mirror surface 218 of a neutral time at an incidence angle of 45° over a full effective width of the mirror surface. In other words, the opening 234 preferably has a size that keeps the light beam from interception. That is, the opening 234 preferably allows the whole light beam to pass therethrough. Moreover, the permanent magnets 268 are preferably disposed not to intercept the light beam incident upon the mirror surface 218 of the neutral time at the incidence angle of 45° over the full effective width of the mirror surface. In other words, the permanent magnets 268 are preferably disposed so as to keep the light beam from interception. Herein, the mirror surface 218 of the neutral time refers to the mirror surface 218 in a state in which the movable plate 214 is not driven at all. Moreover, the effective width of the mirror surface indicates a value obtained by subtracting a width of a portion that might have a processing error,

film forming defect, or the like from a width of the movable plate 214.

[0055] In order to prevent the light beam Bi incident upon the mirror surface 218 of the neutral time with the incidence angle of 45° over the full effective width of the mirror surface from being intercepted, concretely, as shown in FIG. 12, a mirror surface effective width w_m , permanent magnet interval w_p , base opening width w_b , height h_p of the permanent magnet with respect to the mirror surface, and height h_b of an upper surface of the base opening with respect to the mirror surface may satisfy conditions: $w_p > w_m + 2h_p$; and $w_b > w_m + 2h_b$.

[0056] In a layout which satisfies the conditions, the light beam reaches the mirror surface 218 without interception, and therefore there is little loss of light. The layout of the optical deflector upon which the light beam is incident at the incidence angle of 45° is a most general-purpose layout in which other optical members are easily arranged.

[0057] The present inventors actually produced the optical deflector having the mirror surface effective width $w_m = 4.3$ mm (a designed value of a size of the movable plate was 4.5 mm, and a 0.1 mm peripheral area was not included in an effective area because the peripheral area possibly has the processing error, film forming defect, or the like), permanent magnet upper surface interval $w_p = 5.5$ mm, base opening width $w_b = 13.2$ mm, height $h_p = 0.6$ mm of the permanent magnet upper surface with respect to the mirror surface, and height $h_b = 3.6$ mm of the upper surface of the base opening on a trial basis. In the optical deflector produced on the trial basis, a magnetic flux density of about 0.6 (T) was obtained in a position of a driving coil.

[0058] Moreover, in a simulation in which the aforementioned respective parameters were used, a magnetic flux density of about 0.63 (T) was obtained in the position of the driving coil. This value is about 1.6 times a value of a magnetic flux of about 0.39 (T) obtained in a constitution in which the driving coil is disposed at a height corresponding to the height of the upper surface of the permanent magnet.

[0059] As can be understood from the above description, in the optical deflector of the present embodiment, the driving coil 220 is positioned between the upper and lower surfaces of the permanent magnets 268 with respect to a normal direction of the mirror surface 218, and therefore an efficiency is enhanced.

[0060] The optical deflector of the present embodiment has the following advantages.

[0061] According to the optical deflector 200 of the present embodiment, since both the mirror chip 210 and the magnetic circuit 260 are attached to the base 230 on the same side, the inner yoke can easily be disposed in the vicinity of the coil of the movable plate. That is, while the mirror chip 210 is attached to the base 230, no member exists on the surface with the coil formed thereon, that is, the first surface of the mirror chip 210. Therefore, the magnetic circuit 260 including the inner

yoke 266 can easily be designed, and the magnetic circuit 260 can easily be attached.

[0062] Since the mirror chip 210 is bonded to the base 230 utilizing the second surface with the mirror surface 218 formed thereon, that is, the flat surface with no electrode formed thereon, a large bonding area can easily be secured, and the chip can firmly be fixed.

[0063] Since the mirror chip 210 is attached alone to the base 230 with the wiring substrate 240 formed beforehand thereon without requiring any wiring material, the operation efficiency is superior, and the positioning precision is enhanced. Since the mirror chip 210 is connected to the wiring substrate 240 by wire bonding, low cost and high reliability can be realized.

[0064] Respective constitutions of the present embodiment can variously be modified or changed.

[0065] For example, the optical deflector may include a detection element for detecting a speed and angle. For example, the optical deflector may include a detection coil or Hall element formed on the movable plate. Moreover, the optical deflector may include a piezo-resistance element formed on the elastic member, or an electrode, formed on the movable plate or the elastic member, for detecting a change of capacitance. In the optical deflector including the detection element, the portion of wire bonding during assembly increases, but this does not increase the difficulty in wire bonding.

Claims

1. An optical deflector (200) comprising:

a mirror structure (210) having a first surface and a second surface which are in a front/back relation, the mirror structure (210) comprising a pair of supports (212), a movable plate (214) which is moved with respect to the supports (212), and a pair of elastic members (216) for connecting the movable plate (214) and the supports (212), such that the movable plate (214) is able to rock with respect to the supports (212) about the pair of elastic members (216) as a rocking axis;
a single plate base (230) for holding the mirror structure (210); and
driving means (220, 260, 262, 268) for driving the mirror structure (210), the driving means (220, 260, 262, 268) including a conductive element (220) formed on the first surface of the movable plate (214), and magnetic field generating elements (268) fixed on the base (230),

characterized in that

the movable plate (214) has a mirror surface (218) on the second surface, the base (230) has an opening (234) for exposing the mirror

surface (218), and the supports (212) of the mirror structure (210) are fixed to the base (230) with the second surfaces of the supports (212) in contact therewith.

2. The optical deflector (200) according to claim 1, **characterized in that** the supports (212) include electrode pads (224) electrically connected to the conductive element (220), the base (230) includes wiring materials (242, 244, 246) for electric connection to the outside, the wiring materials (242, 244, 246) have connection portions (246) electrically connected to the electrode pads (224), and the electrode pads (224) are electrically connected to the connection portions (246) by wire bonding.
3. The optical deflector (200) according to claim 2, **characterized in that** the base (230) comprises a main substrate (232) having the opening (234), and a rigid substrate (240) fixed to the main substrate (232), and the wiring materials (242, 244, 246) are formed on the rigid substrate (240).
4. The optical deflector (200) according to claim 3, **characterized in that** the rigid substrate (240) is within the main substrate (232).
5. The optical deflector (200) according to claim 3 or claim 4, **characterized in that** the main substrate (232) has conductivity, the wiring materials (242, 244, 246) include a ground wiring (244) for grounding, and the ground wiring (244) is electrically connected to the main substrate (232).
6. The optical deflector (200) according to any one of claims 3 to 5, **characterized in that** the base (230) further comprises a flexible substrate (254) formed integrally with the rigid substrate (240).
7. The optical deflector (200) according to any one of claims 3 to 5, **characterized in that** the base (230) further comprises a flexible lead wire (252) connected to the wiring materials (242, 244, 246) of the rigid substrate (240).
8. The optical deflector (200) according to any one of claims 1 to 7, **characterized in that** the conductive element (220) comprises a coil disposed along a peripheral edge of the movable plate (214).
9. The optical deflector (200) according to claim 8, **characterized in that** the magnetic field generating elements (268) are disposed on the same side of the base (230) as a side on which the mirror structure (210) is mounted.
10. The optical deflector (200) according to claim 8 or claim 9, **characterized in that** the driving means

(220, 260, 262, 268) further comprises a yoke (262) of magnetic material, which cooperates with the magnetic field generating elements (268) to constitute a magnetic circuit (260), and at least a part of the yoke (262) is disposed in the vicinity of the first surface of the movable plate (214).

11. The optical deflector (200) according to any one of claims 1 to 10, **characterized in that** the conductive element (220) is positioned so as to overlap the magnetic field generating elements (268) as viewed from a direction parallel to the first and second surface of the mirror structure (210).
12. The optical deflector (200) according to claim 11, **characterized in that** the base (230) further comprises bonding portions (236) projecting from the main substrate (232), and the mirror structure (210) is fixed to the bonding portions (236) by adhesion, so that the mirror structure (210) is positioned remote from the main substrate (232).
13. The optical deflector (200) according to any one of claims 1 to 12, **characterized in that** the opening (234) of the base (230) has a size that does not intercept the light beam incident upon the mirror surface (218) of a neutral time at an incidence angle of 45° over a full effective width of the mirror surface (218), and the magnetic field generating elements (268) are located not to intercept the light beam incident upon the mirror surface (218) of the neutral time at the incidence angle of 45° over the full effective width of the mirror surface (218).
14. The optical deflector (200) according to claim 13, **characterized in that** the magnetic field generating elements (268) are located interposing the conductive element (220) formed on the first surface of the movable plate (214), and a mirror surface effective width w_m , interval w_p of the magnetic field generating elements, base opening width w_b , height h_p of the of the magnetic field generating elements with respect to the mirror surface (218), and height h_b of an upper surface of the base opening (234) with respect to the mirror surface (218) satisfy conditions: $w_p > w_m + 2h_p$; and $w_b > w_m + 2h_b$.

15. An optical deflector (200) comprising:

a mirror structure (210) having a first surface and a second surface which are in a front/back relation, the mirror structure (210) comprising a pair of supports (212), a movable plate (214) which is moved with respect to the supports (212), and a pair of elastic members (216) for connecting the movable plate (214) and the supports (212), such that the movable plate (214) is able to rock with respect to the supports

(212) about the pair of elastic members (216) as a rocking axis;
a single plate base (230) for holding the mirror structure (210); and
a driver (220, 260, 262, 268) for driving the mirror structure (210), the driver (220, 260, 262, 268) including a coil (220) formed on the first surface of the movable plate (214), and permanent magnets (268) fixed on the base (230),

characterized in that

the movable plate (214) has a mirror surface (218) on the second surface, the base (230) has an opening (234) for exposing the mirror surface (218), and the supports (212) of the mirror structure (210) are fixed to the base (230) with the second surfaces of the supports (212) in contact therewith.

16. The optical deflector (200) according to claim 15, **characterized in that** the opening (234) of the base (230) has a size that does not intercept the light beam incident upon the mirror surface (218) of a neutral time at an incidence angle of 45° over a full effective width of the mirror surface (218), and the permanent magnets (268) are located not to intercept the light beam incident upon the mirror surface (218) of the neutral time at the incidence angle of 45° over the full effective width of the mirror surface (218).
17. The optical deflector (200) according to claim 16, **characterized in that** the permanent magnets (268) are located interposing the coil (220) formed on the first surface of the movable plate (214), and a mirror surface effective width w_m , permanent magnet interval w_p , base opening width w_b , height h_p of the permanent magnet with respect to the mirror surface (218), and height h_b of an upper surface of the base opening (234) with respect to the mirror surface (218) satisfy conditions: $w_p > w_m + 2h_p$; and $w_b > w_m + 2h_b$.

ANNEX TO THE EUROPEAN SEARCH REPORT ON EUROPEAN PATENT APPLICATION NO.

EP 01 12 7261

This annex lists the patent family members relating to the patent documents cited in the above-mentioned European search report. The members are as contained in the European Patent Office EDP file on The European Patent Office is in no way liable for these particulars which are merely given for the purpose of information.
